Optical Sensors

Application Note

Designing the VCNL36826M Into an Application

By Jerry Liu

INTRODUCTION AND BASIC OPERATION

The VCNL36826M is a fully integrated proximity sensor. It combines a high power vertical-cavity surface-emitting laser (VCSEL), photodiode for proximity measurement, and signal processing IC in a single package with a 12-bit ADC. The device provides proximity sensing to minimize accidental touch inputs that can lead to call drops and camera launch.

With a range of up to 20 cm (7.9 in), this stand-alone component greatly simplifies the use and design-in of a proximity sensor in consumer and industrial applications, because no mechanical barriers are required to optically isolate the emitter from the detector. The VCNL36826M features a miniature, surface-mount 2.55 mm by 2.05 mm leadless package (LLP) with a low profile of 1 mm. The device is designed specifically to meet the low height requirements of smartphone, mobile phone, digital camera, and tablet PC applications.

Through its standard I²C bus serial digital interface, it allows easy access to a "proximity signal". The programmable interrupt function offers wake-up functionality for the microcontroller when a proximity change occurs, which reduces processing overhead by eliminating the need for continuous polling.

Fig. 1 - VCNL36826M Top View

Fig. 2 - VCNL36826M Bottom View

COMPONENTS (BLOCK DIAGRAM)

The major components of the VCNL36826M are shown in the block diagram.

In addition to the ASIC with the proximity photodiode, the VCSEL emitter is also implemented. Its cathode is connected to the driver internally and need not be connected externally.

The DNA of tech.

Designing the VCNL36826M Into an Application

The integrated VCSEL emitter has a peak wavelength of 940 nm. It emits light that reflects off an object within 20 cm of the sensor. An added lens helps to increase peak intensity due to enabling a small angle of just \pm 3°, as shown in Fig. 4.

Fig. 4 - Angle of Half Intensity of the Emitter

The VCSEL emitter has a programmable drive current from 8 mA to 20 mA in seven steps. The infrared light is emitted in short pulses with a programmable period time from 10 ms to 80 ms. The proximity photodiode receives the light that is reflected off the object and converts it to a current. It has a peak sensitivity of 850 nm. The sensitivity of the proximity stage is also programmable by choosing from four different integration times. It is insensitive to ambient light. It ignores the DC component of light and "looks for" the pulsed light at the proximity frequency used by the emitter.

The application-specific integrated circuit, or ASIC, includes a VCSEL driver, I²C bus interface, amplifier, integrated analog to digital converter, oscillator, and signal processor. For proximity, it converts the current from the photodiode to a 12-bit digital data output value.

PIN CONNECTIONS

Fig. 3 shows the pin assignments of the VCNL36826M. The connections include:

- Pin 1 connect to ground
- Pin 2 INT to the microcontroller
- Pin 3 NC or connect to ground
- Pin 4 NC
- Pin 5 V_{DD} to the power supply
- Pin 6 V_{DD} to the power supply
- Pin 7 SDA to the microcontroller
- Pin 8 SCL to the microcontroller

The power supply for the ASIC (V_{DD}) has a defined range from 2.74 V to 3.6 V. The VCSEL also needs to be connected to same supply between 2.74 V and 3.6 V, depending on the required current (see detailed description with the datasheet).

On the common power supply, for the V_{DD} and the VCSEL one 1 μ F ceramic capacitor should be placed close to pin 5 and pin 6. The SCL and SDA, as well as the interrupt lines, need pull-up resistors. The resistor values depend on the application and on the I²C bus speed. Common values are about 2.2 k Ω to 4.7 k Ω for the SDA and SCL, and about 8.2 k Ω to 22 k Ω for the interrupt lines.

Fig. 5 - VCNL36826M Application Circuit

2

The DNA of tech.

Designing the VCNL36826M Into an Application

MECHANICAL DESIGN CONSIDERATIONS

The VCNL36826M does not require a mechanical barrier. The signal processor continuously compensates for the light reflected from windows, thus ensuring a proper proximity reading. As a fully integrated sensor, the design process is greatly simplified.

The only dimensions that the design engineer needs to consider are the distance from the top surface of the sensor to the outside surface of the window, and the size of the window. These dimensions will determine the size of the detection zone.

The angle of half intensity of the emitter is about $\pm 3^{\circ}$, as shown in Fig. 6, and the sensitivity of the photodiode is showing about $\pm 55^{\circ}$.

Fig. 6 - Angle of the Half Intensity of the Emitter

Fig. 7 - Angle of the Half Sensitivity of the Photodiode

Fig. 8 - Emitter and Detector Angle

To achieve good performance, the diameter of the hole within the cover glass should not be too small. An angle of \pm 40° will be sufficient in most applications. The package drawing shows the position of the VCSEL and photosensitive area. The \pm 40° lines are set to the outer edges of the photodiode and VCSEL. The following are dimensions for the distance from the top surface of the sensor to the outside surface of the glass, a, and the width of the window, d.

Fig. 9 - Window Dimensions for One Hole

For a single round hole, the diameter should be at least wide enough that the openings can freely look through; so, about 2 mm.

Document Number: 80569 🔳

For technical questions, contact: <u>sensorstechsupport@vishay.com</u> THIS DOCUMENT IS SUBJECT TO CHANGE WITHOUT NOTICE. THE PRODUCTS DESCRIBED HEREIN AND THIS DOCUMENT ARE SUBJECT TO SPECIFIC DISCLAIMERS, SET FORTH AT <u>www.vishay.com/doc?91000</u>

The DNA of tech.

Designing the VCNL36826M Into an Application

The diameter needs to be increased with distances between the sensor and cover glass according to the following calculation.

The width calculation for distances from 0.5 mm to 1.5 mm results in:

a = 0.5 mm	\rightarrow x = 0.42 \rightarrow d = 2 mm + 0.84 = 2.84 mm
a = 1.0 mm	\rightarrow x = 0.84 \rightarrow d = 2 mm + 1.68 = 3.68 mm
a = 1.5 mm	\rightarrow x = 1 26 \rightarrow d = 2 mm + 2 52 = 4 52 mm

Calculation is: $\tan \alpha = x/a \rightarrow \text{with } \alpha = 40^{\circ} \text{ and } \tan 40^{\circ} = 0.84 = x/a \rightarrow x = 0.84 \times a$. Then total width / diameter for the opening is d = 2 mm + 2 × x.

The results above represent the ideal diameters of the window. The mechanical design of the device may not allow for these diameters. Fig. 9 shows that a smaller opening could also be used. To allow for this, the gap between sensor and cover should be as small as possible (≤ 0.2 mm) and the cover also quite thin (≤ 0.6 mm).

PROXIMITY SENSOR

The main DC light sources found in the environment are sunlight and tungsten (incandescent) bulbs. These kinds of disturbance sources will cause a DC current in the detector inside the sensor, which in turn will produce noise in the receiver circuit. The negative influence of this DC light can be reduced by optical filtering, but is reduced much more efficiently by a so-called DC kill function. The proximity photodiode shows its best sensitivity at about 850 nm, as shown in Fig. 10.

Fig. 10 - Spectral Sensitivity of the Proximity Photodiode

50 μ s (PS_IT = 1T) up to 400 μ s (PS_IT = 8T). PS_ITB sets the duration of T in PS_IT. It is recommended to set PS_ITB to 50 μ s because it improves the sensitivity and sunlight protection of the sensor. The period time for this single pulse can be programmed between 10 ms and 80 ms.

In addition to DC light source noise, there is some reflection of the infrared emitted light off the surfaces of the components surrounding the VCNL36826M. The distance to the cover, proximity of surrounding components, tolerances of the sensor, defined infrared emitter current, ambient temperature, and type of window material used all contribute to this reflection. The result of the reflection and DC noise is the production of an output current on the proximity and light sensing photodiode. This current is converted into a count called the offset count.

In addition to the offset count, there could also be a small noise floor during the proximity measurement, which comes from the DC light suppression circuitry. This noise is typically just one or two counts. Only with light sources with strong infrared content could it be in the range from ± 5 counts to ± 10 counts.

The application should "ignore" this offset and small noise floor by subtracting them from the total proximity readings. The VCNL36826M offers a subtraction feature that automatically does this: PS_CANC. During the development of the end product, this offset count is evaluated and may now be written into register 0x07: PS_CANC_L/H. Now the proximity output data will just show the subtraction result of proximity counts - offset counts.

Results most often do not need to be averaged. If an object with very low reflectivity or at longer range needs to be detected, the sensor provides a register where the customer can define the number of consecutive measurements that the signal must exceed before producing an interrupt. This provides stable results without requiring averaging.

The proximity sensor uses a short pulse signal of about

Revision: 25-Apr-2025

4

Document Number: 80569

Designing the VCNL36826M Into an Application

PROXIMITY CURRENT CONSUMPTION

The VCNL36826M is in shutdown by default. It can be turned on by setting $PS_ON = 1$, $PS_CAL = 1$, and $PS_ST = 0$.

The VCNL36826M's embedded VCSEL driver drives the internal VSCEL with a pulsed duty cycle. The VCSEL on / off duty ratio is programmable by an I²C command at register PS_Period. Depending on this pulse / pause ratio, the overall proximity current consumption can be calculated. When higher measurement speed or faster response time is needed, PS_Period may be selected to a short time of 10 ms, but this will then also lead to the highest current consumption:

PS_Period = 10 ms: peak VCSEL current = 20 mA, PS_IT = 1T = 50 μ s, averaged current consumption is 20 mA x 50 μ s/10 000 μ s = 0.1 mA.

For proximity measurements executed just every 80 ms: PS_Period = 80 ms, peak VCSEL current = 20 mA, averaged current consumption is 20 mA x 50 μ s/80 000 μ s = 0.0125 mA.

Another way to execute proximity measurements is to apply a PS active force mode (register: PS_CONF3_L, command: PS_AF = 1).

If only a single proximity measurement needs to be done, PS_AF is set to "1" and then $PS_ST = 0$ = active. Setting PS_Trig = 1 will then execute just one single measurement.

In this mode, only the I²C interface is active. In most consumer electronic applications the sensor will spend the majority of time in sleep mode; it only needs to be woken up for a proximity measurement.

This "active force" mode may be used for even faster measurements than are possible with the self-timed mode. If the lowest possible power consumption is needed, the device should be switched off with 1. $PS_ST = 1$ and 2. $PS_ON = 0$ after every measurement.

LOW POWER CONSUMPTION MODE

With register PS_LPEN set to 1, the proximity sensor operates in a special low power consumption mode offering significantly lower power consumption.

This is a remarkable feature for any application requiring lower power consumption, without the need to always request one proximity measurement with the proximity force mode: PS_AF and PS_TRIG.

The proximity period within this mode can be set between 40 ms and 320 ms. This means 3 to 25 measurements per second can be programmed. "Normal mode" with PS_Period allows only for settings between 10 ms and 80 ms.

PS period (ms)	10	20	40	80	160	320
Normal mode (µA)	600.00	400.00	300.00	250.00	n/a	n/a
Low power mode (µA)	n/a	n/a	107.00	56.00	30.50	17.75

Note

VCSEL_I = 10 mA; PS_IT = 8T

Designing the VCNL36826M Into an Application

With PS_LPEN = 1 = enabled, proximity low power measurements will start. In this case values programmed to PS_LPPER will be used as the period. VCSEL_I, PS_IT, PS_ITB, and PS_MPS will be used, as defined within register 3 and register 4.

20	30.25	17.63	11.31	8.16		20	106.00	55.50	30.25	17.63

With low power mode applied, the VCNL36826M's current consumption reaches a minimum of 6.28 μ A with the longest response time of 320 ms, lowest VCSEL current of 8 mA, and shortest integration time of PS_IT = 50 μ s.

A maximum of 106 μ A is seen when using the fast response time of 40 ms, highest VCSEL current of 20 mA, and longest integration time of PS_IT = 200 μ s.

The pulse length of $PS_IT = 1T$ is 50 µs. The amplitude of that 50 µs pulse is dependent on the VCSEL current. The higher this current is programmed, the higher that pulse amplitude will be. Taking a scope picture with an added series resistor within the power supply line will look like this:

Fig. 11 - Proximity VCSEL Pulse for 1T

Designing the VCNL36826M Into an Application

INITIALIZATION AND I²C TIMINGS

www.vishay.com

The VCNL36826M contains eleven 16-bit command codes for operation control, parameter setup, and result buffering. All registers are accessible via I^2C communication. The built-in I²C interface is compatible with the standard and high speed I²C modes. The I²C H-level voltage range is from 1.65 V to 3.6 V.

There are only four registers out of the eleven that typically need to be defined:

1. VCSEL_I = 8 mA to 20 mA (VCSEL current), and PS_HD = 12 bits / 16 bits (PS output) ⁽¹⁾ REGISTER CONF4 #04 [0x04h]

Note

- (1) 16 bits can be used to increase the dynamic range but cannot be used with the threshold interrupt, which limited to 12 bits
- PS_Period = 6 ms to 20 ms (proximity duty ratio), PS_IT (proximity integration time = pulse length), PS_ITB = 50 μs (IT bank setting of 50 μs recommended for better sensitivity).

PS_PERS (number of consecutive measurements above / below threshold) and PS_ST (PS start) REGISTER PS_CONF2_L and PS_CONF2_H #03 [0x03h]

3. and 4. Definition of the threshold value from the number of counts the detection of an object should be signaled. This is limited to 12 bits for PS output only. Therefore, the threshold with interrupt cannot be used with 16 bits PS output. Proximity TOP Threshold REGISTER PS_THDL_L #05 [0x05h] for the low byte and PS_THDL_H #06 [0x06h] for the high byte.

To define the VCSEL current, as well as the integration time (length of the proximity pulsing), evaluation tests should be performed using the least reflective material at the maximum distance specified.

Fig. 12 shows the typical digital counts output versus distance for three different emitter currents for integration time 1T. The reflective reference medium is the Kodak Gray card. This card shows approximately 18 % reflectivity at 940 nm.

Fig. 12 - Proximity Value vs. Distance for 1T

This first diagram shows the possible detection counts with a short pulse of just 50 $\mu s.$

If higher detection distances and / or objects with very low reflectivity need to be detected, there is the option to extend these proximity pulses up to about 400 μ s for 8T. This results in higher counts but may also lead to saturation effects for very close and very bright objects. This leads then to the diagram in Fig. 13 below.

Fig. 13 - Proximity Value vs. Distance; PS_IT = 8T

With defining the period time (PS_Period), the repetition rate = the number of proximity measurements per second (speed of proximity measurements) is defined. This is possible between 10 ms (about 90 measurements/s) and 80 ms (about 12 measurements/s).

Application Note

Vishay Semiconductors

The DNA of tech.

Designing the VCNL36826M Into an Application

Fig. 15 - Proximity Measurements with PS_Period = 80 ms

This duty cycle also determines how fast the application reacts when an object appears in, or is removed from, the proximity zone.

Reaction time is also determined by the number of counts that must be exceeded before an interrupt is set. This is possible to define with proximity persist: PS_PERS. Possible values are from 1 to 4.

To eliminate disturbances by direct sunlight, these "sunlight cancellation" bits PS_SC need to be set.

To define all these register values, an evaluation test should be performed. These tests can be made just using the VCNL36826M's sensor board, together with the SensorXplorerTM. Both boards are available from any of Vishay's distributors.

Please see:

www.vishay.com/optoelectronics/SensorXplorer.

Timing

For an I²C bus operating at 100 kHz, to write or read an 8-bit byte, plus start (or stop) and bit acknowledgement, takes 100 µs. Together with the slave address byte and the 8-bit command code byte, plus the 16-bit data, this results in a total of 400 µs. When the device is powered on, the initialization with just these five registers needs 5 x 4 bytes (slave address, command register, and 16-bit data) for a total of 20 bytes. So, 20 x 100 µs = 2000 µs = 2 ms.

Send Byte \rightarrow Write Command to VCNL36826M S Slave Address W A Command Code A Data Byte Low A Data Byte High A P

Revision: 25-Apr-2025

Designing the VCNL36826M Into an Application

INITIALIZATION STEPS

It is recommended to follow the following initialization steps to start the most basic proximity measurements using default parameters:

www.vishay.com

1. Do the reset using recommended default values (so that the register will start with default values and will not affect the

setting	of	the	sensor)
PS_CO	NF1_L	=	0x01
PS_CO	NF1_H	=	0x00
PS_CO	NF2_L	=	0x01
PS_CO	NF2_H	=	0x00
PS_CO	NF3_L	=	0x00
PS CO	NF3 H	=	0x00

... the rest = follow the default value like in the datasheet page 8. Only do this for registers that can do R/W only

- 2. Initialize the sensor by setting:
 - I. PS_ON = 1
 - II. (Bit 0 register PS_CONF1_L always stays 1)
 - III. PS_CAL = 1
 - Note
 - Will immediately turn to 0 and will be read as 0 when you read this register
 - IV. (Bit 1 register PS_CONF1_H need to be set to 1) V. $PS_ST = 0$
- 3. Read proximity data register 0xF8

Note

The above register values are intended / valid for the most basic / default values to turn on the sensor. If different sensor parameters (e.g. different VCSEL current / integration time etc.) are being chosen, the values of the register when being read will be different

INTERRUPT

The VCNL36826M features a very intelligent interrupt function. The interrupt function enables the sensor to work independently until a predefined proximity event or threshold occurs. It then sets an interrupt which requires the microcontroller to awaken. This helps customers reduce their software effort, and reduces power consumption by eliminating polling communication traffic between the sensor and microcontroller.

The interrupt pin, pin 2, of the VCNL36826M should be connected to a dedicated GPIO of the controller. A pull-up resistor is added to the same power supply that the controller is connected to. This INT pull-up resistor may be in the range of 8.2 k Ω to 100 k Ω .

The events that can generate an interrupt include:

- 1. A lower and an upper threshold for the proximity value can be defined. If the proximity value falls below the lower limit or exceeds the upper limit, an interrupt event will be generated. In this case, an interrupt flag bit in the read-out register 0xF9 will be set and the interrupt pad of the VCNL will be pulled to low by an open drain pull-down circuit. In order to eliminate false triggering of the interrupt by noise or disturbances, it is possible to define the number of consecutive measurements that have to occur before the interrupt is triggered
- 2. A too high infrared level, such as from strong direct sunlight or close halogen / incandescent lamps, can be observed with checking the bit: PS_SPFLAG

Application Example

The following example will demonstrate the ease of using the VCNL36826M sensor.

Offset

During development, the application-specific offset counts for the sensor were determined. As previously mentioned, the offset count is affected by the components surrounding the VCNL36826M, the window or cover being used, the distance from the sensor to the cover, and emitter intensity, which is controlled by the forward current.

In the following example, with a cover over the sensor, setting the emitter current to 20 mA, and with PS MPS = 8 pulses, the offset counts are 300 counts (Fig. 17). Offset counts vary by application and can be anywhere from 0 counts to several hundred counts. It is important to note that the offset count may change slightly over time due to, for example, the window becoming scratched or dirty, or being exposed to high temperature changes. If possible, the offset value should occasionally be checked and, if necessary, modified.

The DNA of tech.

Designing the VCNL36826M Into an Application

Power Up

As mentioned, there are four variables for proximity measurement that need to be set in the register when the sensor is powered up: the emitter current, the number of occurrences that must exceed a threshold to generate an interrupt, the threshold values, and the number of proximity measurements per second.

The sensor should detect skin at a distance of 5 cm. Development testing determined that a current of 20 mA produces adequate counts for detection. The proximity measurement rate is set so that about 14 measurements are done within a second and the number of occurrences to trigger an interrupt is set to four. Based on development testing, with a hand or skin approximately 5 cm above the window cover, the resulting total count is > 500. This will be used as the upper threshold (high threshold).

For smartphone applications it would be typical to initially set this top threshold and a lower threshold (bottom threshold). This is needed to indicate the removal of the phone from the user's ear. The measured counts without any additional object close by will be around this offset count value, always below the lower threshold value, as shown in Fig. 18.

By setting the number of occurences before generating an interrupt to 4, a single proximity value above or below the thresholds will have no effect, as shown in Fig. 19.

A smartphone application will use a proximity sensor to detect when the phone is brought to the user's ear and disable the touchscreen and turn off the backlight. For other applications, such as automatic dispensing, the soap or towel will be dispensed.

In smartphone applications, the bottom threshold will also be programmed and wait for an interrupt signal. The prox_threshold_bottom should be set to "1" now and the prox_threshold_top cleared by entering a "1" again, since the phone is already next to the user's ear. A lower threshold will occur when the phone call is complete and the phone is brought away from the user's ear, and the backlight and touchscreen will be turned back on.

For this example, the upper threshold will be set to \geq 500 counts. The lower threshold is set to 400 counts; a value that is higher than the offset but low enough to \geq indicate the removal of the phone from the user's ear.

The VCNL36826M has three interrupt modes, which are "normal" interrupt mode, "first high" mode, and "logic high / low" mode. The user has to set the bit 3 : 2 within the register PS_CONF2_L. The description of each of the interrupt modes is as follows:

- 1. The "logic high / low" interrupt mode is selected with PS_INT = trigger by logic high / low mode (0x03_L, bit 3 : 2 = 0 : 1) within register PS_CONF2_L. When this mode is selected, the interrupt pin is pulled low (logic high) when the proximity counts reach the programmed high threshold (PS_THDH) and will return to a high level (logic low) when counts drop below the count value for low threshold (PS_THDL). There is no corresponding interrupt flag for this mode.
- 2. The "first high" interrupt mode is selected with PS_INT = first high (0x03_L, bit 3 : 2 = 1 : 0) within register PS_CONF2_L. In this mode, the initial interrupt event that is triggered needs to be with regard to the high threshold (PS_THDH). Passing underneath the low threshold will have no effect until the first high threshold event has occurred. Therefore, the interrupt pin will be pulled low when the proximity counts first increase beyond the programmed high threshold (PS_THDH), and simultaneously, the interrupt flag in the interrupt register will be set to "1". On the other hand, after the first PS_THDH event, the interrupt pin will also be pulled low when the proximity counts drop below the programmed low threshold (PS_THDL) and simultaneously, the interrupt flag in the interrupt register will be set to "1". The interrupt line will be pulled high again and the interrupt flag will be cleared to "0" once the interrupt register has been read.
- 3. The "normal" interrupt mode is selected with PS_INT = interrupt enabled (0x03_L, bit 3:2 = 1:1) within register PS_CONF2_L. When this mode is selected, the interrupt pin will be pulled low when the proximity counts increase beyond the programmed high threshold (PS_THDH), and simultaneously, the interrupt flag in the interrupt register will be set to "1". On the other hand, the interrupt pin will also be pulled low when the proximity counts drop below the programmed low threshold (PS_THDL), and simultaneously, the interrupt register will be set to "1". The interrupt line will be pulled high again and the interrupt flag will be cleared to "0" once the interrupt register has been read. The sequence of which interrupt event occurs first either PS_THDH or PS_THDL does not play a role, unlike the "first high" mode.

Document Number: 80569

The DNA of tech.

Designing the VCNL36826M Into an Application

Some measurements and features are shown with the demo tool and demo software with a cover glass at about a 1 mm distance.

1. Proximity set-up with 8T wide pulses, 20 mA VCSEL current, PS_MPS = 8, and a period of 80 ms, which results in about 15 measurements per second

Fig. 23 - Screenshot of VCNL36687 Demo Software

2. If a hand or skin now comes as close as 5 cm, these 300 counts rise up to more than 500 counts

Fig. 24 - Hand at About 5 cm Distance Will Lead to More Than 500 Counts

The DNA of tech.

Designing the VCNL36826M Into an Application

3. Here the thresholds are programmed as 500 for the upper and 400 for the lower. To see these, both "Show" buttons are activated. The presence of an object should only be recognized when four consecutive measurements are above that threshold

Fig. 25 - "Settings" Menu Within Demo Software

4. Just one or two measurements above the threshold will not activate the interrupt

Fig. 26 - Upper and Lower Threshold Set and Hand at About 5 cm Distance

The DNA of tech.

Designing the VCNL36826M Into an Application

5. With more than four measurements above the threshold, however, the interrupt is pulled low, as indicated by the red LED on the demo board and the red light: "Int Pin Triggered PS"

Fig. 27 - Hand at About 5 cm Distance for More Than 4 Consecutive Measurements Above Higher Threshold

6. The cancellation feature is used below. The "before seen" offset counts are subtracted. To do so, the value of 300 is entered for register number 05 = Prox_Cancellation

Fig. 28 - Cancellation Activated

APPLICATION

Z O

-1

The DNA of tech.

Designing the VCNL36826M Into an Application

7. The "before seen" offset counts of about 300 are now subtracted: 300 - 300 = 0. Also, the thresholds are now 300 counts lower. The higher threshold is 200 and lower is just 100

Fig. 29 - New Defined Thresholds With Cancellation Feature

If one chooses "logic mode" now and redefines the high threshold to 200 and low threshold as 100...

Designing the VCNL36826M Into an Application

... the interrupt will indicate the rise above the upper threshold and will also automatically be cleared when it falls below the lower threshold.

SMART PERSIST

One special feature for faster proximity measurements is also implemented, which is called "smart persist."

This feature reduces the total reaction time until the interrupt is set to active, although four consecutive measurements should be above (or below) the defined threshold for safe acknowledgment.

Without "smart persist", but with programmed hits above the defined threshold set to four, it will take three times the time of PS_Period. With PS_Period set to 40 ms this would be 3 x 40 ms.

Fig. 31 - Interrupt Active After 4 Hits Above Threshold

With "smart persist" activated (bit 1 of PS_CONF2_L):

REGISTER: PS_CONF2_L DESCRIPTION					
REGISTER NAME		COMMAND CODE: 0x03_L (0x03 DATA BYTE LOW)			
Command	Bit	Description			
PS_Period	7:6	(0 : 0) = 10 ms, (0 : 1) = 20 ms, (1 : 0) = 40 ms, (1 : 1) = 80 ms PS sample period setting			
PS_PERS	5:4	(0 : 0) = 1, (0 : 1) = 2, (1 : 0) = 3, (1 : 1) = 4 PS interrupt persistence setting			
PS_ INT	3:2	(0:0) = interrupt disable, (0:1) = logic high / low mode, (1:0) = first away, (1:1) = interrupt enable			
PS_SMART_PERS	1	0 = disable PS smart persistence, 1 = enable PS smart persistence			
PS_ST	0	0 = PS start, 1 = PS stop, default = 1			

or within the demo-tool:

The total needed time is reduced to just about 7 ms.

Fig. 34 - Smart Persist With Four Consecutive Proximity Pulses Shortly After Each Other

Designing the VCNL36826M Into an Application

MULTI PULSE FEATURE

For high detection ranges, the intensity for each proximity measurement will be chosen to the maximum possible value. This can be achieved by programming the VCSEL current to a maximum of 20 mA and the longest measurement pulse PS_IT of 400 µs.

Even further increases are possible using this so-called Multi-Pulse feature, PS_MPS.

With this it is possible to send more than one pulse for a single proximity measurement. As shown within the table and illustrated with Fig. 34 and Fig. 35 below, a burst with either 2, 4, or even 8 pulses one after the other is possible.

REGISTER: PS_CONF2_H DESCRIPTION					
		COMMAND CODE: 0x03_H (0x03 DATA BYTE HIGH)			
Command	Bit	Description			
PS_IT	7:6	(0:0) = 1T, (0:1) = 2T, (1:0) = 4T, (1:1) = 8T			
PS_MPS	5:4	(0 : 0) = 1, (0 : 1) = 2, (1 : 0) = 4, (1 : 1) = 8; PS multi-pulse setting			
PS_ITB	3	0: ITB = 25 μs, 1: ITB = 50 μs			
PS_HG	2	0 = disable, 1 = enable, PS high gain mode			
Reserved	1:0	Default = (0 : 0)			

With PS_IT of 400 μ s and PS_MPS = 8, this needs then about 6 ms for one measurement (see Fig. 34 below). Fig. 35 shows it with 4 pulses and Fig. 36 shows 8 pulses within a period of 80 ms.

Fig. 35 - PS_IT = 8T (400 $\mu s)$ and MPS = 8

Fig. 36 - PS_IT = 8T (400 $\mu s)$ and MPS = 4

Fig. 37 - PS_Period = 80 ms and PS_IT = 8T (400 $\mu s)$ and MPS = 8

With this much higher energy, the detection distance could be increased up to about 40 cm (15 in).

Designing the VCNL36826M Into an Application

Fig. 38 - Proximity Value vs. Distance for PS_IT = 8T (400 $\mu s)$ and MPS = 8

AUTO CALIBRATION

This new feature offers a direct and internal subtraction of the so-called "offset" counts that are seen when the sensor is built-in within its end application, in which at least the cover will show significant offset counts.

To use this feature, "PS_AC" needs to be set to "1" = enable.

This auto calibration is carried out then with this specific AC parameters that need to be chosen before: PS_AC_Periode and PS_AC_Num. Possible periods are much faster than ones for normal proximity measurements, between 3 ms and 24 ms. The auto calibration is then done when PS_AC_TRIG is set. The whole procedure is shown within Fig. 39.
